VIC FORTH™
By Tom Zimmer

FORTH is an interactive language that is many times faster than BASIC, yet is easier to use than assembly language. FORTH programs are modular permitting structured programming and are extremely efficient in memory usage.

VIC FORTH is a complete implementation of the popular Fig version of FORTH.

RAM expansion is optional.

Extensive instruction manual included.
VIC FORTH is an exciting new cartridge for your VIC 20 computer. You now have a language that is more powerful than BASIC and easier to program than assembler! Some of VIC FORTH's major features are: ability to define your own words; this means a function not already supported can be created by you and added to VIC FORTH for future use. Full VIC sound and color capabilities are built into VIC FORTH. Names for your words may be up to 31 characters, unlike BASIC, which supports only 2 characters.

VIC FORTH comes with a superb full-screen editor which has 16 lines of 64 characters each (standard FORTH screen), using a horizontal scrolling window. VIC FORTH is an interactive language that is very memory efficient and much faster than BASIC.

VIC FORTH will run in a standard VIC 20, although extra memory is recommended. Programs can be loaded or saved from tape or disk. Character output can be sent to any device, including the VIC printer. Up to 24K additional bytes of memory can be automatically used in VIC FORTH. VIC FORTH is a nearly complete implementation of the "FORTH INTEREST GROUP" (fig) version of FORTH. The VIC FORTH editor follows closely the standard FORTH editor described in the book, "STARTING FORTH," plus it has many, many additional features.

1.0 INTRODUCTION

This manual describes the VICFORTH system for the COMMODORE VIC-20 computer. It is an extension of the FORTH Interest Group (fig) model of the language FORTH.

1.1 REQUIREMENTS

HARDWARE  The VIC-20 must have at least 5K bytes of memory (which is available on a standard VIC-20), and VICFORTH will automatically adjust to more memory if you have it. The 3K ram expansion cartridge does not provide any additional memory for VICFORTH to use.

1.2 VICFORTH STARTUP

1. Verify the power is OFF!!.
   *****NEVER INSERT OR REMOVE A CARTRIDGE*****
   ***** WITH THE POWER ON !!!!!! *****
2. Plug the cartridge into the slot on the back.
3. ONLY THEN turn on the power.
   The computer will start up with the VICFORTH sign on message in dark blue characters on a cyan background, with a green border. VICFORTH is now in control.
1.3 FIRST IMPRESSIONS

After VICFORTH is started as described previously, the FORTH operating system is running, with its compiler, interpreter, and text editor. If you press the RETURN key a few times, you will notice an 'CK' is printed after each RETURN is pressed. FORTH is just telling you that it recognized your request to do nothing, and has returned for your next command. In FORTH a line of input text is simply a line of commands, each separated by a space, which FORTH recognizes as command separator. Each command in the line is performed from left to right. If all commands are performed without encountering an error, then FORTH returns with the 'CK' prompt to tell you its mission was accomplished. If an error is encountered at any time during execution, then all processing stops, FORTH will issue an error message and wait for further instructions.

1.4 WHAT IS VICFORTH?

VICFORTH is an implementation of fig-FORTH with the addition of several words to interface to the VIC's sound and color capabilities. Over 250 WORDS are included in VICFORTH, and since FORTH is extensible, you can add many of your own commands to VICFORTH. If you have not used the FORTH language before, you will probably find FORTH's syntax to be somewhat strange. But don't let that bother you; the FORTH programming environment has been honed over a period of 12 years into a very efficient system. In BASIC where some arithmetic operators have different precedences, it is sometimes hard to remember which functions are performed first. To alleviate this problem BASIC uses parentheses to specify the order.
of operation. FORTH does not need to worry about such things, it uses a straight left to right process.

VICFORTH also contains words to allow you to control the character, border, and background colors of the screen.

Five sound control words are provided to allow manipulating the sound output in the VIC-20.

All I/O and several other words are VECTORED, to allow their function to be changed at runtime. This will allow you to drive a printer or other device using I/O that the system may not know exists. As an example, a driver routine could be written to drive a parallel printer over the user port.

In FORTH the term 'WORD' refers to an identifiable function or command, which in some computer languages is referred to as a subroutine or procedure.

In VICFORTH WORDS may be any length from one to thirty-one characters in length. This allows very descriptive names to be used in writing your programs. FORTH programs can then be much easier to read, than basic. It is important to note however that program readability is the responsibility of the person writing the program, and it is just as easy to write programs with all single character names, thus making them almost impossible to decipher. The use of readable names for your VICFORTH words is highly recommended.
1.5 NEW USER OF FORTH OR A VETERAN

We wish to state very clearly that this manual is NOT A FORTH BEGINNERS MANUAL!! If you are a newcomer to the FORTH world, VICFORTH provides all of the program tools you will need to learn the FORTH language, BUT there are several books which you should purchase that will better lead you in learning the FORTH language. These books are as follows:

1. STARTING FORTH
2. fig-FORTH INSTALLATION MANUAL
3. fig-FORTH 6502 ASSEMBLY SOURCE LISTING
4. FORTH-79 STANDARD CONVERSION

The first two are highly recommended, and will provide you with most of the needed tutorial information. All of these manuals are available from the FORTH INTEREST GROUP.

Another point worth stressing is that the STARTING FORTH manual listed above is the best tutorial manual available today, BUT it describes a version of FORTH called FORTH-79, which is not identical to fig-FORTH/VICFORTH. So you should read the section of this manual called FORTH-79 DIFFERENCES while using the book, to assist you in learning FORTH. Also, the publication FORTH-79 STANDARD CONVERSION will be helpful in running the more complex examples in the STARTING FORTH book.

1.6 WHAT IS THE FORTH INTEREST GROUP

The FORTH INTEREST GROUP is an independent group of FORTH enthusiasts whose aim is to educate others, answer technical questions and to promote FORTH.
They may be contacted at:

PO Box 1105  Phone for orders:
San Carlos, CA 94070 (415) 962-8653

They publish a newsletter FORTH DIMENSIONS ($15/yr)
and have many other publications available.

2.0 VICFORTh SYSTEM CONFIGURATION

The following describes some of the aspects of how
the VICFORTh system is organized and how it is
similar and/or dissimilar to other FORTH systems.

NOTICE!!! If you are a complete beginner to
FORTH, you should probably skip this section for
now, and go to the book STARTING FORTH which you
should have purchased. Just start working through
the book. Do not be afraid of experimenting! The
program in the cartridge cannot be damaged by any
programming error. Just press RUN/STOP RESTORE to
restart if required.

NOTATION The following symbol terminology is used
throughout this manual. The $ sign is used in place
of the # symbol, ie the one above the 3 key.

<table>
<thead>
<tr>
<th>SYMBOLS</th>
<th>MEANING</th>
</tr>
</thead>
<tbody>
<tr>
<td>al or addr1</td>
<td>16 bit address</td>
</tr>
<tr>
<td>n, n1, or n2</td>
<td>16 bit signed number</td>
</tr>
<tr>
<td>d1, d2</td>
<td>32 bit signed double number</td>
</tr>
<tr>
<td>u1, u2</td>
<td>16 bit unsigned number</td>
</tr>
<tr>
<td>b1</td>
<td>8 bit byte</td>
</tr>
<tr>
<td>c, c1</td>
<td>7 bit ascii character</td>
</tr>
<tr>
<td>f, f1</td>
<td>Boolean flag</td>
</tr>
</tbody>
</table>

(C) 1982 Human Engineered Software
tf True boolean flag -- 1
ff False boolean flag -- 0
string, t Ascii text string
<sp> Space character
$return$ The RETURN key

STACK VALUES (b --- t ; a)

b The stack before the word executes.
--- The word being executed.
t The ascii string which follows the word
; Denotes the place where the <return>
in some cases.
key would be pressed.
a The stack after the word executes.

STACK PARAMETER DESCRIPTIONS

n1/n2/n3

The value n1 was placed on the stack first,
then n2, then n3. The notation is read "n1 under n2
under n3". n3 is on top of the stack.

EXAMPLE:

In the description of a FORTH word called
<example>, the following might appear:

a1/n1/n2 --- t ; a2

This would be interpreted as follows:
Before the word <example> is executed there are
three items on the stack with n2 being the last
placed on, n1 being the previous one, and a1 being
the earliest one. The '---' represents the word
<example> being executed, where 't' is text which

(C) 1982 Human Engineered Software
must follow <example> before <return> is pressed at the ';' symbol. After the execution of the word <example>, the stack is left with one item 'a2'.

2.1 MEMORY ALLOCATION

VICFORTH will run on any COMMODORE VIC-20 computer with 5K to 29K bytes of user read/write (ram) memory. About 2K bytes of the available ram is used by the system, (FORTH & the KERNEL) so in a 5K VIC-20 this leaves about 3K bytes for the users program. The available ram is then divided into two segments. The first segment is screen/block buffer space; this area holds the source text for any program you enter. The second segment is called the dictionary; it holds the object code of any program you have compiled.

On a 5K VIC, VICFORTH will initialize itself with 2K bytes allotted to screen buffer space (which is equal to two screens), and 1K bytes for dictionary space. Since a compiled program is generally much smaller than the source which created it, a two screen (2K) source program should compile into 1K of dictionary space without difficulty.

There can, however, occur situations where you would like to have more than 1K of dictionary space. If this occurs, you can resegment the user ram with the system word "EBLOCKS". This word allows you to specify how many screens of buffer space you will have in the system. Any reduction in screen buffer space results in an increase in dictionary or compiled program space. The following command will allot one screen buffer, and return an additional 1024 bytes of ram to the dictionary.
The **`LBLOCKS`** command clears out any program in the dictionary before resegmenting the user ram, so any program already compiled will be lost, effectively a **COLD** start is performed. The **`LBLOCKS`** command is normally executed right after powerup.

If your VIC-20 has more than 5K bytes of ram (excluding the 3K ram cartridge, which **VICFORTH** cannot access), **VICFORTH** will automatically expand the number of screen buffers up to six screens. A screen in **VICFORTH** is 1024 characters, or bytes of memory. In a fully expanded VIC-20 with 29K bytes of user memory, you may specify up to 26 screen buffers, to allow editing very large programs.

The command **`LBLOCKS`** always truncates the number of screens you request to within the range one to the maximum that memory will allow minus one; this assures there will always be at least 1K bytes of dictionary space.

### 2.1.1 **STACK SPACE**

The system stacks are located near the bottom of memory. The **DATA** stack is located in page zero, from about $60$ (numbers preceded by $\$, like $60$, indicate a hexadecimal number) down to $10$, giving room for about 40 data stack entries. The **RETURN** stack is located in page one, the 6502 hardware stack. It shares this page with the terminal input buffer, and is thus limited to about 60 decimal levels of nesting. These stacks should be large enough for any properly developed program.
2.2 BLOCK INPUT/OUTPUT

The word BLOCK in the language FORTH provides the user with a method of accessing a very large data or program storage area typically on disk, as if all of the storage area were in the user ram memory space. In VICFORTH where a disk is typically not available, this process is simulated by allocating an area of user memory for the virtual screen buffers, and limiting the range of the area a user can access to the amount of screen buffer space currently specified. This technique allows many of FORTH's virtual memory operations to be performed normally, but within the restriction of user memory. The BLOCK command is a member of the list of vectored words in VICFORTH, and it's definition can be changed by the user.

In a disk based FORTH system the word BLOCK just described would perform the reads and writes to disk automatically. In this cassette-based system however, screens are read or written to cassette by the user using the READ and WRITE words described later in this chapter.

2.3 SYSTEM CALLS

COMMODORE has built into the VIC-20 a very powerful KERNEL. In BASIC, you do not have access to the KERNEL, since it must be passed several parameters in the machine registers to control the operation of a KERNEL call. In VICFORTH, however, a word 'SYS' has been provided which allows you to set all of the machine's registers including the status of the CARRY FLAG, before performing a system call. Once the call returns, the contents of all CPU registers is placed on FORTH's stack, and is available to you. This very versatile word allows you to access all
KERNEL functions from high level FORTH.

SYS (<f>/n1/n2/n3/a1 -- <f>/n4/n5/n6 )
The SYS command allows calling any assembly language routine. 'f' is an optional CARRY set/reset flag; it is returned unmodified. n1, n2, and n3 are the A,X,Y registers respectively, and return their routine modified contents. a1 is the call address. Any called routine must return with an assembly 'RTS' instruction, and must not destroy the hardware stack contents. Here is an example of a system call to the VIC KERNEL:

   HEX
   : MESSAGES.OFF 0 0 0 FF90 SYS 3DROP ;

This word will turn off all KERNEL messages, for errors, and warnings, etc. VICFORTH is initialized with all messages ON. The "0 0 0" in the above definition are the mandatory "A,X,Y" register values. The address "FF90" is the call address for the system call we are performing. The word SYS performs the system call, and the 3DROP after SYS removes the returned values of the "A,X,Y" registers after the call is performed, off the stack.

Here is a list of predefined system calls available in VICFORTH.

SETFLS (n1/n2/n3 --- ) Set system logical file command, must be sent n1, the user assigned file\$\$, n2 the device number assigned to the file\$\$, and n3 the command to be sent to the device. See the "VIC PROGRAMMERS REFERENCE MANUAL".

OPEN ( --- ) Open the device and file\$\$ specified in the previous SETFLS command.

(C) 1982 Human Engineered Software
SAVE (al/n1 ---)  Save to cassette from memory at address al, for a count of n1 bytes, as the file last specified by SETFLS.

SLOAD (al ---)  Load from cassette to memory at address al, the file last specified by SETFLS. The load buffer area must be large enough for the file being loaded.

CHKOUT (n1 ---)  Send all character output to device n1. Device n1 must have been previously opened.

CLALL (---)  Clear all channels and devices, restore all I/O to video and keyboard.

SETNAM (al/n1 ---)  Set the name at address 'al', as the current file name, for a length of 'n1' characters. See also section 7.0, VICEFORTH AND DISK.

2.4 CASSETTE INTERFACE

Five words have been included in the system to permit easy writing and reading of data to and from cassette. These are:

READ (n1 ---)
READS (n1/n2 ---)
WRITE (n1 ---)
WRITES (n1/n2 ---)

In these words, n1 is the first SCREEN or BLOCK to read or write. n2, when present, is the number of SCREENS or BLOCKS to read or write.
DON'T FORGET TO SETUP THE CASSETTE RECORDER!

The fifth word is -

LOADS ( nl --- )

nl screens will be loaded from cassette, and compiled or interpreted. Each SCREEN will be read into BUFFER $1$, and then a LOAD is performed. Then the next SCREEN is read and loaded, etc. This procedure was chosen so that only a single buffer would be required, in order to have the system function with minimal memory. This means that very large programs may be loaded. The number nl specifies the number of screens to be read and loaded, and it must match the actual number of screens on the cassette.

Two additional words direct the device number, and the file number to be used with READ and WRITE operations. These are "DL" and "FL". They are initialized to 1 by VRESET, for normal cassette operation. If you wish to direct READ/WRITE I/O to a device other than cassette, you will need to change the contents of these variables. See also section 7.0 on VICFORTH DISK OPERATION.

2.5 DOWN-LOADED WORDS

Two words in VICFORTH are DOWN-LOADED to RAM from ROM. They are:

FORTH and EDITOR

These two words are what are called VOCABULARIES. They contain a variable which changes as new words are added to the dictionary. For these variables to
function correctly they must be in RAM, so both of these words are DOWN-LOADED. The total code that is moved is less than 60 bytes.

2.6 WHAT IS MISSING

There are several fig-FORTH words which are not in this system. For the most part these are words which are used for the DISK interface. They are not needed in this implementation. They are:

```plaintext
BUFF R/W INDEX TRIAD Prev Use
FLUSH UPDATE Empty-Buffers (Abort) Warning
```

If desired, an EXPERIENCED PROGRAMMER can add these and change the VECTOR for BLOCK.

2.7 NEXT

For those interested assembly language programmers, NEXT is located with the following code sequence:

```
'(LOOP) NFA 2 - @ CONSTANT NEXT
```

Here a constant has been created with the name NEXT for future program reference.

2.8 MEMORY MAP

```

(C) 1982 Human Engineered Software
3.0 EDITOR

3.1 EDITOR COMMENTS

The EDITOR in VICFORTH is modeled after the editor described in the introductory book STARTING FORTH by L. Brodie.

Note: For the examples in the book STARTING FORTH and the discussion in this manual, use screens numbered 1 to 6 on an 8K expanded system, or screens 1 and 2 on a nonexpanded system.

You can now start the edit session by entering the following:

```
n1 <sp> EDIT <return>
```

The EDITOR vocabulary is selected and the BACKGROUND color has switched to WHITE, indicating the editor has been selected. The screen will be split in two - the top 16 lines are used for entering text (edit area) and the bottom 6 for entering edit commands (command area). If you just turned on the computer, you will have 16 lines of garbage at the top of the screen. To clear out the edit buffer in preparation for editing, type:

```
WIPE <return>
```

This will clear the edit screen to all spaces. While in the editor, the window around the cursor is always displayed just before the next command line is fetched from the keyboard, so you always have an updated view of what your edit commands are doing to the text. You will also notice two double-digit numbers displayed in the lower right corner of the edit window. The rightmost number is the column..."
position of the cursor in the edit screen, the left number is the number of the current edit screen. The cursor keys are also redirected in the editor, so they allow you to scan around through the edit screen with very little effort. To leave the EDIT mode, just press RUN/STOP RESTORE, and the edit mode will be terminated.

For a complete discussion of the use of the editor commands you should refer to the book STARTING FORTH, although it is similar enough to a typical fig-FORTH editor that an experienced FORTH programmer should be able to use the editor with just the abbreviated discussion presented in the next section.

Note: Three characters are viewed incorrectly in the edit window.

```
[ is + ] is | @ is -
```

### 3.2 AN EDITOR EXAMPLE

This editor contains both Screen and Line edit commands. The line edit commands have been taken directly from STARTING FORTH, and are described in that book. The screen edit commands give you the ability to see the form of the text as it is entered into the edit screen. To enter the screen edit mode, press the <shift> key, and the <INST/DEL> key. The border of the screen will switch to yellow (lighter grey on a b/w TV), and is now waiting for you to type any text you wish inserted into the screen. Type the following:

```
THIS IS VICFOR<!--TH <F5> -->TH
```

(C) 1982 Human Engineered Software  17
The text THIS IS VICFORTH was inserted in line zero of the screen, and when you pressed \( \text{<F5>} \) (F5 is the tan function key labeled F5), the cursor moved to the beginning of the next line. The \( \text{<F5>} \) function key is like \( \text{<return>} \), in that it moves the cursor to the next line, but it leaves you in the INSERT mode. If you accidentally pressed \( \text{<return>} \), you will have noticed the border switch back to GREEN, indicating you have left the INSERT mode. To repeat, you must press \( \text{<return>} \) to exit the INSERT mode, at which time the border will switch back to the normal GREEN. While in the INSERT mode, the \( \text{<del>} \) key is enabled to delete characters before the cursor in the edit window, rather than characters on the command lines at the bottom of the screen.

3.2.1 AN EDITOR EXAMPLE (contd)

Type in the following edit commands in the edit mode to get a feel for the different edit commands.

```
1 EDIT
WIPE
3 T
P THIS IS A LINE OF TEXT
K
P THIS IS A LINE OF TEXT.
U HERE IS ANOTHER ONE
3 T
F TEXT
E
5 T
P THIS IS ANOTHER ONE ONE.
F ANOTHER
R ANOTHER LINE
D ONE
```
1 DEL
4 T
F A
TILL ER
8 T
P HERE IS A TEST LIST
F LIST
E
8 T
D TEST
I NEW LINE
3 T P EXAMPLE OF TWO COMMANDS
X

To leave the editor, type one of the following:

FORTH  ( Terminate the session )
VRESET  ( Reset all I/O vectors )

--- or ---

hit RUN/STOP & RESTORE (Reselects FORTH and resets I/O vectors)

3.3  EDITOR WORDS

LINE EDITING COMMANDS
From STARTING FORTH editor:

<table>
<thead>
<tr>
<th>WORD</th>
<th>FUNCTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>T ( nl --- )</td>
<td>Sets the edit pointer to the start of line nl.</td>
</tr>
<tr>
<td>P ( --- &lt;t&gt; ; )</td>
<td>Text following space after P is placed into line holding edit pointer.</td>
</tr>
</tbody>
</table>

(C) 1982 Human Engineered Software
U (---<t>; ) Text following space after U is placed under the current line and all lower lines are moved down.

M (nl/n2--- ) Copies current edit pointer line UNDER line n2 in screen nl.

X (---) Deletes line containing the edit pointer and moves lower lines up one. Line E15 becomes blank. The line is held in PADI.

Added from fig editors:

H (---) Holds the edit pointer line in PADI.

K (---) Kills (erases) the edit pointer line.

S (---) Spreads the lines at the edit pointer. All lines from the edit pointer are moved down. Line 15 is lost.

TOP (---) Move edit pointer to TOP of screen.

NOTE: In (---<t>; ), The <t> symbol indicates the text is optional. Typing <return> without any text will use the current contents of PADI, or PADF.

EDITING COMMANDS
From STARTING FORTH editor:

<table>
<thead>
<tr>
<th>WORD</th>
<th>FUNCTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>F (---&lt;T&gt;; ) Find first occurrence of text following 'F'. Starts at current edit pointer.</td>
<td></td>
</tr>
</tbody>
</table>
E ( --- ) Erases as many characters going backward as the length of the last 'F' command.

D ( --- ) Deletes the first occurrence of text following the D command, searches from edit pointer till end of screen.

TILL ( --- <t> ; ) Deletes all text starting at edit pointer until and including the string following the command TILL. Works on current LINE only. If string is not found, no delete occurs.

I ( --- <t> ; ) Inserts text following the command I into the edit buffer at the current position of the edit pointer. Text following that is too long for the line is lost.

R ( --- <t> ; ) Replaces the string just found by 'F' with the string following the R command.

Additions to the editor:

DEL ( nl --- ) DELetes nl characters BEFORE the edit pointer, and compresses the line to omit the space.

C ( nl --- ) Move the cursor by the signed amount nl characters (positive for forward move, negative for backward move). This word also redispays the current edit window.

N ( --- ) Move the edit pointer to the top of the next higher screen buffer. Limited by BMNX.

B ( --- ) Move the edit pointer to the top of the previous (lower) screen buffer. Limited by
EDIT (nl --- ) Selects the edit mode, with nl as the screen to be edited. Moves the edit pointer to the top of screen nl. Revectors CR & KEY to show the current edit window, and make cursor keys functional.

MISCELLANEOUS EDITOR WORDS

These words are not normally used from the keyboard. They are provided to allow editor expansion.

(F) (--- ) Search for text in PADF till end of screen.

(I) (--- ) Insert the current contents of PADI into the edit buffer at the cursor. Text too long for the line is lost.

PADF (--- al ) Returns address of find buffer.

PADI (--- al ) Returns address of insert buffer.

PAD (--- al ) Returns address of scratchPAD area al.

TEXT (cl --- t ; ) Accepts the text following the command TEXT into the scratchPAD area until the character with ASCII value cl.

GTEXT (al --- ) Accepts text from input stream until a delimiting \[ enter \] is found, or the \[ enter \] key is pressed. The text is placed at address al.

!CUR (nl --- ) Sets the edit pointer to

(C) 1982 Human Engineered Software
value \( nl \). (\( nl \) is limited to \( 0 \leq nl \leq 1023 \).

**Additional immediate key functions:**

**Cursor keys**  
Active, allow scanning through the edit buffer character by character, or with auto repeat.

**HOME key**  
Moves the cursor to the top of the edit screen.

**Function keys:**

F1  
Tab cursor right 4 characters.

F3  
Tab cursor left 4 characters.

F5  
Move cursor to beginning of next line.

F2  
Move edit to the Next higher screen number.

F4  
Move edit Back to the previous screen number.

F7  
Find the next occurrence of search string given by the last 'F' command and leave insert mode if not found.

F8  
Replace the most recently found string with the text specified in the most recent 'R' command.

\(<\text{INST}>\)  
This key enables the INSERT mode, the BORDER color is changed to YELLOW to indicate the insert mode, and all keys are inserted into the edit screen as they are typed. The <DEL> key is also enabled, to delete characters on the edit screen preceding the cursor. The <return> key leaves the INSERT mode, and the BORDER color returns to GREEN.

(C) 1982 Human Engineered Software 23
4.0 VICFORTH SPECIFICS

4.1 COLOR CONTROL

VICFORTH provides you with words to control the background, border, and character color of the VIC-20, without having to poke into memory using an obscure calculation. The background is controlled as follows:

   nl <sp> BACKGROUND <return>

Where nl is a number in the range 0 to 15, giving 16 possible background colors. The border is controlled as follows:

   nl <sp> BORDER <return>

Where nl is in the range 0 to 7, giving 8 possible border colors. The border colors are the same as the character colors, listed on the front of the top row of keys. Just subtract one from the key number to select the proper color. EXAMPLE:

   7 <sp> BORDER <return>

The above command will select a YELLOW BORDER color.

The character color is selected in the same manner as BASIC. Press the CTRL key, and the color key (1-8), to select the character color you desire. The color key pressed is also placed in the command stream, although it is not a printable character. To select the color of characters to be printed during program execution, first find out what the KEY value is for the color desired, as follows:

24 (C) 1982 Human Engineered Software
KEY <return>
   ↑2  ( the up arrow two is CTRL 2) 
   . <return> ( will print the value of the key ) 
   5 ( printed by the computer as the value ) 
   ( of the control 2 key. )

Now all that is required since we know the value of 
the key to select the color we want, is to EMIT it:

   5 EMIT <return> ( this will select WHITE 
characters, )
   ( this can be put in a program too! )

To switch colors to another color, simply EMIT the 
value for that color.

Color word glossary:

BGROUND  ( nl --- )  The value nl in the range 
0 to 15 sets the BackGROUND color of the screen. 
Refer to the VIC-20 Users Manual for color value 
selection.

BORDER  ( nl --- )  The value nl in the range 
0 to 7 sets the BORDER color. The value of nl is the 
same as the keyboard keys 1-8, minus one 1, i.e., 7 
is YELLOW and 2 is RED.

EMIT  ( nl --- )  Sends ASCII value nl to 
the current output device (usually the screen). See 
Appendix J of the VIC User Manual for possible 
values. The values to EMIT to select the different 
character colors are:

   BLK = 144  WHT = 5  RED = 28
   PUR = 156  GRN = 30  BLU = 31

(C) 1982 Human Engineered Software
CYN = 159      YEL = 158

By the way, the SCREEN in VICFORTH is always located at $1000, regardless of how much memory your system has.

4.2 SOUND CONTROL

Words have been included to control the VOLUME and frequency of all four of the VIC-20's voices. The VOLUME is controlled as follows:

nl <sp> VOLUME <return>

The value of nl is used to select the volume of all voices currently active. Values 0 to 15 are valid.

The frequency of the four voices are controlled by storing values into the name of the voice to be turned on. The names are

ALTO     TENOR     SOPRANO     NOISE

The voice is turned on by storing a value greater than 128 decimal into the desired voice. Values 128 to 254 generate increasingly higher frequencies, while a value of 255 will generate the lowest frequency for a given voice. To generate a middle C on the TENOR voice, enter the following:

10 <sp> VOLUME <return>
195 <sp> TENOR <sp> C! <return>

If the volume is turned up on your television, you will hear a note being generated. To turn OFF the voice, simply store a zero into it:

(C) 1982 Human Engineered Software
The voice will be silenced.

Sound control glossary:

VOLUME ( nl --- ) Sets the VOLUME of all voices as the value of nl. nl is in the range 0 to 15. 15 is loudest and 0 turns all voices off.

ALTO
TENOR
SOPRANO
NOISE ( --- al ) Constants which return the address al of the tone voices of the VIC-20. Each voice is programmed for frequency by storing an 8 bit value in the range 128 to 255 into its address.

EXAMPLE:

195 <sp> TENOR <sp> C! <return>

The above will turn on the middle voice of the VIC-20. Any value less than 128 will turn off the voice.

4.3 USER PORT

COMMODORE has provided a full 8 bit port in the VIC-20, and we have included a constant which returns the address of the DATA register of that port. The name of the word is UPORT, and it can be used to access 8 bits of external data. This port is initialized as an INPUT port, so any TTL level can be observed as follows:

UPORT <sp> C@ <return>

(C) 1982 Human Engineered Software
This will place the value of the data on the port on the FORTH data stack. Once the data is on the stack, it can be printed, or manipulated in many ways. If you wished to use the UPORT as an OUTPUT port, you will have to initialize UPORT as follows:

255 <sp> UPORT <sp> 2+ <sp> C! <return>

This stores a binary value of all ones into the UPORT data direction register of the 6522 VIA chip in the computer. The VIA is designed to make any data bits output, when the corresponding bits have been set to one in the data direction register.

To control the output data from the port:

nl <sp> UPORT <sp> C! <return>

Where nl is a number in the range 0 to 255, which is to be sent to the user port.

User port glossary:

UPORT ( --- al ) Returns the address al of the user port.

4.4 PRINTING OUTPUT

VICFORTH includes words to allow data or programs to be listed to the serial printer. The word PRINT allows any character output from the line of text following PRINT to be sent to the serial printer, then after that line is interpreted, output returns to the video screen. A lower level word PRON turns
on the printer port, and leaves all character output going to the serial printer, till a CLALL (clear all) command it executed. These commands would be used within your program to control printer output.

To list a screen to the printer:

    PRINT nl LIST

where nl is the desired screen number.

Since all I/O is vectored in VICFORTH, it is also possible to write a printer driver for other types of printers than are supported by the VIC KERNEL. Vectored I/O will be discussed in a later section.

**Printer output glossary:**

**PRON** ( --- ) Send all character output to the printer port.

**CLALL** ( --- ) Restore all KERNEL I/O to their default values - keyboard and video.

**PRINT** ( --- t ; ) Any character output from the line of text following the **PRINT** command, will be channeled to the printer port. When the line completes interpretation, output will be restored to the video.

**NOTE:** If an **ERROR** is encountered in the **PRINT** command line, all character output will remain on the printer. To restore character output to the video screen, type:

    CLALL <return>

(C) 1982 Human Engineered Software
This will clear the print buffer, and return character output to the video screen.

NOTE: DO NOT USE THE PRINT WORD FROM WITHIN THE EDITOR!! The CR word is revectored by the editor, and will cause your listings to be printed without carriage returns.

4.5 SCREEN BUFFER CONTROL

Memory is a precious commodity in a small computer, and it needs to be used efficiently. In line with this, VICFORTH includes a method of reallocating use memory such that efficient use can be made of the limited resources available. Three words are provided to control memory usage. They are:

BMX EMPTY $BLOCKS

BMX is a user variable, which contains the highest block number the system will allow you to access. It is initialized at COLD start to a value of six on a 13K system, and two on a 5K system. Due to memory restrictions a 5K system is limited to 2 screen buffers. The following applies to larger machines. A 13K machine can have up to 10 screen buffers, which leaves very little for program compilation, but which allows large programs to be edited. To select a different number of screen buffers than is set at COLD start, perform the following:

7 <sp> $BLOCKS <return>

The system now is configured for seven screen buffers, with the dictionary space reduced accordingly to four. $BLOCKS first sets the value
of $\text{BMAX}$, after limiting it to the amount of memory you have, then calls $\text{EMPTY}$ to reset memory, and empty out the dictionary of any current program.

The word $\text{EMPTY}$ can also be used from the keyboard, when you have been experimenting with some new definitions, and you would like to clean out the dictionary.

Screen buffer control glossary:

$\text{BMAX} \quad (\ldots \ a1) \quad$ A user variable which contains the highest block the user can currently access.

$\text{EMPTY} \quad (\ldots ) \quad$ Resets the $\text{VOCABULARY}$ pointers to their $\text{GOLD}$ start values, and resets the dictionary pointer to $\text{LIMIT}$.

$\text{\#BLOCKS} \quad (\ n1 \ \ldots ) \quad$ Select $n1$ as the current number of screen buffers for the system. Limits $n1$ to the range 1 to max that memory will allow.

4.6 $\text{VLIST}$

The word $\text{VLIST}$ in $\text{VICFORTH}$ as in $\text{fig-FORTH}$ gives you a list of all of the commands currently available. The word is executed by simply typing its name:

\[ \text{VLIST} \ <\text{return}> \]

You will then see a vertical list of words, each having an address to its left. The address is the Parameter field address of the word, and can be useful in experimenting with $\text{VICFORTH}$'s internals. If you press any character key on the keyboard, the scrolling list of words will pause until another key

(C) 1982 Human Engineered Software
is pressed or RUN/STOP is pressed to cause the VLIST to stop.

4.7 ADDITIONAL UTILITIES

Here are some additional utility definitions contained in VICFORTH.

DUMP ( al/ nl --- ) This utility is provided to allow you to dump the contents of memory to the screen in a byte format. The contents of memory are printed in the current base, with four numbers per line and an address to the left. An example follows:

    HEX <return>
    A000 8 DUMP <return>
    A000 XX XX XX XX
    A004 XX XX XX XX

Where al is the starting address of the DUMP, and nl is the number of characters to display.

THRU ( nl/ n2 --- ) Screens numbered nl through screen n2 are all loaded in sequence, from the memory buffers. These screens must have all been previously read in from cassette.

ASCII ( --- t ; ) The first letter of the text word following will be placed on the stack when in the interpret mode, or compiled into the dictionary if in the compile mode.

EM ( --- al ) This is a system variable, which returns the address in memory where the end of memory pointer resides. Here is a simple
definition to calculate the amount of free memory in the dictionary and print that value:

: .FREE EM @ HERE -. ;

U. ( nl --- ) Prints the value of nl unsigned.

H. ( nl --- ) Prints the value of nl as an unsigned hexadecimal value.

5.0 VECTORS

5.1 WHAT ARE THEY?

As you may have learned by now, FORTH is a macro language, that is, FORTH is made up of many simple words written in assembly language. These are used to create powerful words, by stringing several smaller words together in a line. This simple technique makes FORTH a very powerful tool in writing programs. There is one small problem with this method though - there are times when a low level word needs to perform a slightly modified function, so a higher level word can also do something a little differently. As an example, suppose you had a parallel printer. Since the VIC-20 has an 8 bit user port, it would be nice to be able to send all of your listings to that port, rather than the video screen. The only problem with this is that the VIC-20 KERNEL doesn't know about your printer on the USER port, and can not easily be made to talk to it. In VICFORTH this will not be a major problem. All I/O in VICFORTH is vectored, so you can make all character output from FORTH go to your own routine rather than just the routines that the VIC-20 already knows about.

(C) 1982 Human Engineered Software
5.2 VECTORED WORDS IN VICFORTH

VICFORTH has included a minimum set of words which should fill the needs of most users wishing to revector various operations in FORTH. Here is a list of all of the VECTORED words in VICFORTH, and their positions in the two vector tables, I/O, and WORDS.

<table>
<thead>
<tr>
<th>Position</th>
<th>Word</th>
</tr>
</thead>
<tbody>
<tr>
<td>HEX</td>
<td>DECIMAL</td>
</tr>
<tr>
<td>00</td>
<td>00</td>
</tr>
<tr>
<td>02</td>
<td>02</td>
</tr>
<tr>
<td>04</td>
<td>04</td>
</tr>
<tr>
<td>06</td>
<td>06</td>
</tr>
<tr>
<td>08</td>
<td>08</td>
</tr>
<tr>
<td>0A</td>
<td>10</td>
</tr>
<tr>
<td>0C</td>
<td>12</td>
</tr>
<tr>
<td>0E</td>
<td>14</td>
</tr>
<tr>
<td>10</td>
<td>16</td>
</tr>
<tr>
<td>12</td>
<td>18</td>
</tr>
<tr>
<td>14</td>
<td>20</td>
</tr>
<tr>
<td>16</td>
<td>22</td>
</tr>
<tr>
<td>18</td>
<td>24</td>
</tr>
</tbody>
</table>

Note: User created vectored words start at an index of 30, and may consist of up to 20 total vectors, two bytes each.

5.3 VECTOR CONTROL

Here is an example of how to revector the character output to a different device than the video screen.
We will give an example of a printer driver for the USER port, for a seven (7) bit printer driver, with the eighth (8th) bit used as a strobe.

The first thing we need is a word to initialize the port for all 8 bits as outputs:

( --- ) ( initialize the user port )
: PINIT 255 UPORT 2+ C! O UPORT C! ;

Next we need a word to send characters to the user port and strobe bit 8 of the port:

( --- ) ( Strobes bit 8 of user port )
: STROBE8 UPORT 128 TOGGLE UPORT 128 TOGGLE ;

( nl --- ) ( Send char to user port )
: PORTOUT 127 AND UPORT C! STROBE8 ;

Now we have a routine to send characters to the USER port, all we have to do is vector EMIT to the new character output word.

: TO.UPORT ' PORTOUT CFA I/O 2+ ! ;

The routine above takes the CFA (code field address) of the new driver word, and stores it into the third and fourth bytes of the I/O vector table in user memory. The instant this has been done, any further character output will be going to the new driver routine. If it doesn't work, then the program may hang. To restore the I/O vectors to their initial values hit RUN/STOP & RESTORE or type VRESET. Either of these will restore all of the VECTORS to their initial values.

NOTE: The example above was to show how to revector

(C) 1982 Human Engineered Software
EMIT. It was not an example of a complete printer driver, since most printers require handshaking that I did not include. You will have to study the data sheets on the 6522 chip for a while before attempting such a driver.

**Vector Word Glossary**

**VECTOR** (n1 --- t ; ) This is a new defining word, used to add additional words to VICFORTH that are to be vectored. It is used as follows:

```
30 <sp> VECTOR <vector name>
```

After the above is executed, any time <vector name> is executed, it will execute the routine whose CFA is in I/O + 30. You must therefore store the CFA of a valid dictionary word into it before executing <vector name>.

Note: User VECTORs are from 30 to 50 decimal.

**VWORDS** ( --- al ) This word returns the address al of the beginning of the initial value vector table in ROM. This data may be accessed in the same manner as the I/O table to obtain the actual routine's CFA for a given vectored word.

I/O ( --- al ) This word returns the address al of the beginning of the user vector table in RAM. This table is used to change the function of selected dictionary words.

**VRESET** ( --- ) This word when executed RESETS all of the vectored dictionary words to their initial values, by moving the data at VWORDS to the
RAM table at I/O.

6.0 ERRORS, CRASHES AND OTHER PROBLEMS

6.1 ERROR MESSAGES

VICFORTH is an 8K byte program. In an effort to include as many user features as possible, we have had to omit lengthy error messages. Here then is a list of the error numbers, and the error messages to go with them.

<table>
<thead>
<tr>
<th>ERROR</th>
<th>ERROR MESSAGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEC</td>
<td>HEX</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>8</td>
<td>8</td>
</tr>
<tr>
<td>17</td>
<td>11</td>
</tr>
<tr>
<td>18</td>
<td>12</td>
</tr>
<tr>
<td>19</td>
<td>13</td>
</tr>
<tr>
<td>20</td>
<td>14</td>
</tr>
</tbody>
</table>

(C) 1982 Human Engineered Software
21   15  THIS WORD IN A PROTECTED
    DICTIONARY.
You can't forget anything below FENCE.

22   16  USE ONLY WHEN LOADING.

23   17  EDIT POINTER IS OFF CURRENT EDIT
    SCREEN.

24   18  DECLARE YOUR VOCABULARY.
Specify the VOCABULARY on which you wish to perform
the operation in, IE: FORTH or EDITOR.
The VIC-20 KERNEL has several I/O errors that can
occur, these will be printed out as follows.

    I/O_error 5

The above example indicates an attempt to talk to a
device which is not in the system. like a disk, or
printer. here is a full list of the errors that can
be printed by the KERNEL. These message numbers are
always printed in DECIMAL.

<table>
<thead>
<tr>
<th>I/O error</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td>9</td>
<td>ILLEGAL DEVICE NUMBER.</td>
</tr>
</tbody>
</table>

6.2 WHAT DO I DO WHEN IT CRASHES?
VICFORTH provides a much more powerful programming environment than BASIC. Unfortunately it also places a higher level of responsibility on you, the programmer, than BASIC. There are many ways to cause FORTH to GO AWAY! When this happens, there are several ways to recover. If the crash is relatively minor, you can press RUN/STOP RESTORE, and FORTH will sign back on as if nothing has happened. There are however some cases when this will not work. If this happens, turn off the power, and then turn it back on after a few seconds, and VICFORTH will restart. It is advisable to save any large program to cassette tape prior to attempting to execute it. This may save you a lot of time later.

6.3 MESSAGE

Message is vectored in VICFORTH, so although full length error messages are not built into the system, one can add full length error messages by revectoring MESSAGE to a user written procedure. Type the following lines into screen 1, but don't type in the line numbers.

0 DECIMAL (NEW MESSAGE ROUTINE)
1 : NEW MESSAGE OR CALL ( N1 --- )
2   DUP 0 = IF." WHAT?" ENDIF
3   DUP 1 = IF." STACK EMPTY!" ENDIF
4   DUP 2 = IF." MEMORY SPACE EXHAUSTED" ENDIF
5   DUP 8 = IF." BLOCK RANGE ERROR" ENDIF
6   DUP 17 = IF." FOR COMPILING ONLY" ENDIF
7   DUP 18 = IF." FOR EXECUTING ONLY" ENDIF
8   DUP 19 = IF." IMPROPER CONDITIONALS" ENDIF
9   DUP 20 = IF." INCOMPLETE DEFINITION" ENDIF
10  DUP 21 = IF." THIS WORD PROTECTED" ENDIF
11  DUP 22 = IF." USE ONLY WHEN LOADING" ENDIF

(C) 1982 Human Engineered Software
12  DUP 23 = IF ." CURSOR OFF SCREEN" ENDIF
13  DUP 24 = IF ." SPECIFY THE VOCABULARY" ENDIF
14  SP! QUIT ;
15  : FULL ' NEW.MESSAGE CFA I/O 18 + ! ; FULL
    DECIMAL ;S

The above definition will now be inserted into the VECTOR for MESSAGE, as shown in line 15 above. To reinstate the messages after any warm start type: FULL <return>.

6.4 FORTH-79 DIFFERENCES

VICFORTH is a fig-FORTH implementation of the FORTH language. The differences between VICFORTH and FORTH-79 will be covered here on a chapter by chapter basis of "STARTING FORTH" to help you understand and adjust to the difference.

STARTING FORTH

Pg. 12,13 Change the definition of MARGIN to:

: MARGIN CR 5 SPACES ;

The VIC-20 has a narrow screen. The above change will improve the appearance of the demo.

Pg. 60 The screens in VICFORTH are numbered 1 to 6. An unexpanded VIC-20 has screens 1 and 2.

Pg. 68 Remember that lines in VICFORTH longer than 22 characters will wrap around. VICFORTH still has 64 character lines internally.

Pg. 76 FLUSH This word is not needed in this cassette-based system.
Pg. 77  S  The editor 'S' command is not included, due to space restriction. Use the 'F' (find) command. In VICFORTH the 'S' command is used for Spread a line, which makes room at the current edit line for additional text to be inserted.

Pg. 83  Here is the VICFORTH definition for a stack print utility:

HEX
60 VARIABLE S0
: DEPTH SP@ S0 @ SWAP - 2 / ;
: .S ?STACK OR DEPTH
   IF SP@ 2 - S0 @ 2 -
   DO I @ 5 .R - 2
   +LOOP
   ELSE ." EMPTY " ENDIF ;

Pg. 91  0>  This operator not supported, use ' 0> '. (leave a space )

Pg. 101  ?DUP  Not supported use -DUP.
         ABORT"  not supported, use:
         IF ." ERROR MESSAGE " SP! QUIT ENDIF

Pg. 107  1-  2-  2*  2/  Not supported, use:
         1 - 2 - 2 * 2 / (leave a space)

Pg. 110  I' and J are not supported, here are their definitions:
         : I' R> R> R SWAP >R SWAP >R ;
         : J R> R> R SWAP >R SWAP >R ;

Pg. 143  PAGE  Not supported, here is the definition:

(C) 1982 Human Engineered Software 41
DECIMAL : PAGE 147 EMIT ;

U.R Not supported, here is the definition:
: U.R 0 SWAP D.R ;

Pg. 153 2* and 2/ not supported. Use 2 * and 2 /

Pg. 161 /LOOP Not supported in VICFORTH.

Pg. 164 DOUBLE NUMBER DELIMITERS. VICFORTH only recognizes the decimal point "," as a double number delimiter.

Pg. 173 Only D+, D.R supported, for DNEGATE use DMINUS.

Pg. 174 Only M* and M/ supplied, but use the definitions in the fig-FORTH installation manual for these words.

Pg. 183 VARIABLE The definition of VARIABLE used in VICFORTH is the fig-FORTH definition, which requires an initial value to be on the stack before creating the variable.
EXAMPLE:

12 VARIABLE DATE

This will create a variable with an initial value of 12.

Pg. 193 2VARIABLE, 2CONSTANT, 2@, and 2! are not supplied in VICFORTH. See 79-STANDARD conversion.

Pg. 207 CREATE This word functions

42 (C) 1982 Human Engineered Software
differently in VICFORTH/fig-FORTH than in this book, use the following to create the definition of LIMITS as shown in the book.

220 VARIABLE LIMITS 340 , 170 , 100 , 190 ,

NOTE: The rule of thumb is to use VARIABLE in place of CREATE for definitions which DO NOT have DOES> in them. If the definition is of the form:

CREATE xxx DOES> xxx
then use: <BUILDS xxx DOES> xxx

This conforms to the fig-FORTH usage.

Pg. 216 FIND and EXECUTE VICFORTH uses the fig-FORTH word -FIND in place of FIND. In fig-FORTH the word EXECUTE must receive the code field address (CFA) instead of the parameter field address (PFA). Change the example on this page as follows:

' GREET CFA EXECUTE <return>

FORTH responds with:

HELLO I SPEAK FORTH OK

Pg. 217 VECTORED EXECUTION The techniques will work on VICFORTH with the modification that the addresses obtained with '(tick) are converted to code field addresses (CFA) by the use of CFA. Example, line 6 would read:

' HELLO CFA 'ALOHA !

SAY The definition of SAY in VICFORTH is:

(C) 1982 Human Engineered Software 43
:SAY [COMPILE] ' CFA 'ALOHA ! ;

There are two changes here. The word ' (tick) is used, and because in fig-FORTH it is IMMEDIATE, it must be compiled by the [COMPILE] word. The second change is the use of CFA to prepare the address for EXECUTE.

Pg. 219 NUMBER This definition is vectored in VICFORTH but to revector NUMBER as shown on this page, in VICFORTH you must say:

DECIMAL ' (number) I/O 10 + !

VICFORTH uses a table, where each entry in the table does not have to have a header. Again due to space restrictions.

[ ' ] This word is not supported in VICFORTH. Functionally it is the same as ' (tick).

Pg. 220 NAME LENGTHS VICFORTH supports full names up to 31 characters in length.

Pg. 230 EXIT In VICFORTH use ;S.

Pg. 232 RELOAD is not needed, all code is in ROM.

Pg. 233, 237 H In VICFORTH use DP.

Pg. 235 'S In VICFORTH use SP@.

Pg. 239 OPERATOR Not needed in VICFORTH.

Pg. 240 >IN Use IN in VICFORTH.
OFFSET Not needed in this cassette

44 (C) 1982 Human Engineered Software
VICFORTH.

Pg. 243 ASSEMBLER The assembler may be loaded from cassette, if required.

Pg. 245 LOCATE Not supported in VICFORTH.

Pg. 255-257 UPDATE, FLUSH, SAVE-BUFFERS, EMPTY-BUFFER, BUFFER These words are not in VICFORTH since it is cassette based.

Pg. 259 LABEL In VICFORTH, must change to:

: LABEL 8 * ' "LABEL" 3 + + 8 TYPE SPACE ;

VICFORTH does not support ['] and the word ' (tick) serves the same function in a definition.

Pg. 261 >TYPE Not needed in VICFORTH, use TYPE.

Pg. 266 MOVE, <CMOVE Not in VICFORTH.

Pg. 272 H Use DP.

Pg. 281 -TEXT In VICFORTH use (MATCH), see fig-FORTH installation manual for its definition.

Pg. 291 VARIABLE, CREATE To create the STARTING FORTH type of definition for VARIABLE, use:

: VARIABLE <BUILDS 2 ALLOT DOES> ;

To create the VICFORTH/fig-FORTH definition for VARIABLE, you do it this way:

: VARIABLE <BUILDS , DOES> ;

(C) 1982 Human Engineered Software
The fig-FORTH word CREATE is used only for creating CODE word headers.

Pg. 292  DEFINING WORDS  The definition of a DEFINING-WORD in the book must be changed to:

: DEFINING-WORD <BUILDS (compile-time action)
DOES>  (run-time action);

The EXAMPLE for CONSTANT is then:

: CONSTANT <BUILDS , DOES> @ ;

Pg. 297  ARRAY The definition of ARRAY must be changed to:

: ARRAY <BUILDS OVER , * ALLOT
DOES>  DUP @ ROT * + + 2+ ;

Pg. 313  DOES>  For most purposes VICFORTH is the same as FORTH-79, but for the advanced programmer, see the document FORTH-79 STANDARD CONVERSION from the FORTH INTEREST GROUP.

Pg. 332  JOB, 1FIELD, 2FIELD These must change to account for the different CREATE, use:

20 VARIABLE JOB  24 ,
00 VARIABLE 1FIELD 30 ,
30 VARIABLE 2FIELD 12 ,

Pg. 339  SIMPLE FILES In screen 240 change the definitions as follows:

00 VARIABLE SURNAME 16 ,
16 VARIABLE GIVEN  12 ,

(C) 1982 Human Engineered Software
FREE  

Change the definition of FREE to the following:

: FREE 1 MAXRECS 0
  DO I $RECORD ! RECORD QD 33 <
     IF 0= LEAVE ENDIF
   LOOP
     IF "$ FILE FULL "$ QUIT ENDIF ;

Pg. 339 ' (tick) Prefix all occurrences of ' with the word [COMPILE], EXAMPLE:

: CHANGE [COMPILE] ' PUT ;

Pg. 347 DENSITY, THETA, STRING Prefix all of the words when defined with a zero (0).

7.0 VICFORTH AND DISK

The VICFORTH system as supplied to you is specifically designed to work with cassette, but since some people are likely to want to use the VIC-20 with the 1540 disk drives, here are some routines that will allow you to save programs on the disk drive.

DECIMAL (select the decimal number base)

(select the CASSETTE for further operation)

: CASSETTE 0 0 SETNAM 1 DL ! 1 FL ! ;

(Select the DISK for further operation)

: DISK 0 0 SETNAM 8 DL ! 15 FL ! ;

(Write screen nl to the name following

(C) 1982 Human Engineered Software 47
(n1 --- t ;)
: NWRITE NAME WRITE ;

(Read screen n1 with name following NREAD)
(n1 --- t ;)
: NREAD NAME READ ;

Usage of these routines is very simple. Enter them into a screen and save them on cassette for later use. When you wish to load or save screens to disk, load in these routines from cassette, put a formatted disk into the 1540 disk drive.

Load a created file from cassette, or create a file you wish to send to disk, then perform the following;

DISK <return>

This selects all READ and WRITE operations to go to the DISK.

1 <sp> NWRITE <sp> TEST1 <return>

The above command will write screen 1 to disk with the name TEST1. All files on disk must have names, although they can have numbers for names.

When you wish to read TEST1 back into a screen enter the following command line.

2 <sp> NREAD <sp> TEST1 <return>

TEST1 will be read into screen 2. To rewrite TEST1 back to the same filename, you must prefix the name with the "@" sign as follows:
2 <sp> WRITE <sp> @TEST1 <return>

Screen 2 will be written back to disk, overwriting the original contents of file TEST1.

To reselect the cassette for further I/O operations execute the following command;

CASSETTE <return>

The cassette device will be reselected, and the filename will be reset to NO-NAME as is normal for cassette block I/O.

A disk to be used with VICFORM can be initialized using the normal built in BASIC technique.

NAME HANDLING GLOSSARY

FN ( --- al ) A user variable which returns a pointer to the beginning of a 64 byte buffer, used to hold the current FILENAME.

SETNAM (al/n1 ---) See SYSTEM CALLS section 2.3.

NAME ( --- t ; ) Selects the text following NAME up to a delimiting up arrow or a <return> as the current FILENAME for any READ or WRITE operation on CASSETTE, or DISK. The sequence-

0 0 SETNAM <return>

will reset the current FILENAME to no name.

8.0 USEFUL UTILITIES

(C) 1982 Human Engineered Software 49
Here is the source for several useful definitions you might need in experimenting with your VIC-20. These are NOT in VICFORTH, but may be entered into an edit screen and saved to CASSETTE or disk.

HEX ( --- d1 ) ( returns a double number time)
: ?TIME 0 0 0 FFDE SYS >R 100 * + R> ;

DECIMAL ( x1/y1 --- x2/y2 ) ( scales to screen coord )
: SCALE 23 - 4 / SWAP 32 - 4 / SWAP;

HEX ( x1/y1 --- ) ( move cursor to x,y )
: XY SWAP 0 0 2SWAP FFF0 SYS 2DROP 2DROP ;

HEX ( --- a1 )
( Returns the base address a1 of the VIC I/O )
: IOBASE 0 0 0 FFF3 SYS ROT DROP 100 * + ;

(---) (Load the current edit screen)
: TRY SCR @ LOAD ;

(---nl) (Return the amount of free memory)
: FREE EM @ HERE - ;

(nl --- ) (Close file number nl)
:CLOSE 0 0 FFC3 SYS 3DROP ;

( d1/d2 --- d1/d2/d1 )
( Duplicate the double number d1 over top of )
( double number d2. )
:2OVER >R >R 2DUP R> R> 2SWAP ;

DECIMAL (Select the decimal number base.)
( --- f1 )

50 (C) 1982 Human Engineered Software
( Read the joystick and return a boolean flag. )
: J0 37137 QA 4 AND 0= ;
: J1 37137 QA 8 AND 0= ;
: J2 37137 QA 16 AND 0= ;
: J3 37154 128 TOGGLE 37152 QA 128 AND 0= 37154 128 TOGGLE ;
: FIRE 37137 QA 32 AND 0= ;

( --- x/y )
( Read the analog paddles, and return x and y. )
: PADDLEXY 36872 @ 256 /MOD ;

( --- )
( Toggle the auto repeat switch in the system. )
( Causes all keys to repeat when held down. )
( WARNING: May also cause some keybounce. )
: AUTO.REPEAT 650 128 TOGGLE ;

HEX

(--- nl)
( Read the system status byte, see the )
( PROGRAMMERS REFERENCE MANUAL. )
: STATUS 0 0 0 FFB7 SYS 2DROP ;

HEX

( Turn on RS-232 port at 300 baud )
( Use CLCALL to restore OUTPUT to SCREEN )
: SERIAL.ON 6 293 C! 0 294 C! ( Set baud and parity )

293 2 SETNAM ( Tell them to the system )
2 2 0 SETFLS ( Set the logical file )
OPEN ( Open the channel to RS-232 )
2 CHKOUT ; ( Direct output to the channel)

DECIMAL ( Select the Decimal number base. )
( Generate a short tone )
: BEEP 10 VOLUME ( Set the volume of the tone )

(C) 1982 Human Engineered Software
293 TENOR C! ( Turn on the TENOR voice =
293 )
1000 0 DO LOOP ( Wait a short time )
0 TENOR C! ; ( Turn off the TENOR voice=0 )

9.0 VICFORTH ALPHABETIZED GLOSSARY

You can obtain a complete glossary of all fig-FORTH words by requesting it from the FORTH INTEREST
GROUP, whose address is given in Section 1.6. Below
is a glossary of VICFORTH words that do not appear
in the fig glossary.

LIBLOCKS ( nl --- )
Clears out memory, and sets the number of screen
buffers to value nl, after clipping nl to within the
limits (1) and the max memory will allow minus 1.

(MATCH) ( addr1/addr2/nl --- f1 )
Compare the strings at addr1 and addr2 for length nl
for equality. Return boolean flag f1 true for
match, and false for no-match.

2DROP ( d1 --- )
Drop the double number from the top of the stack.

2DUP ( d1 --- d1/d1 )
Copy the double number on the top of the stack. The
duplicate becomes the new top of stack.

2SWAP ( d1/d2 --- d2/d1 )
The position of the two double numbers on top of the
stack is swapped.

3DROP ( nl/n2/n3 --- )
Drop the three 16 bit values from the stack, used in
system calls to clean off the stack.
\[ = \quad (n1/n2 \quad \text{---} \quad f) \]
Leave a true flag if \( n1 \) is less than or equal to \( n2 \). Otherwise, a false flag is left.

ALTO \quad (\quad \text{---} \quad \text{addr1}) \quad \text{P}
Return the address of the alto voice in the VIC chip. Values between 128 and 255 turn this voice on.

ASCII \quad (\quad \text{---} \quad n1) \quad \text{P}
Smart word, compiles char following into dictionary as a literal if in compile state, else places its value on the stack.

BGROUND \quad (\quad n1 \quad \text{---} \quad \text{)}
Select value \( n1 \) as the current BackGROUND color.

BMAX \quad (\quad \text{---} \quad \text{addr1}) \quad \text{S}
A system variable containing the highest value BLK is allowed to assume. If \( \text{BLK} \) is greater than \( \text{BMAX} \), an appropriate error message is issued.

BORDER \quad (\quad n1 \quad \text{---} \quad \text{)}
Select value \( n1 \) as the current BORDER color.

CHKOUT \quad (\quad n1 \quad \text{---} \quad \text{)}
Set file number \( n1 \) as the current terminal output device for all character output. See PRON, and PRINT. The file number \( n1 \) must have been previously opened.

CLALL \quad (\quad \text{---} \quad \text{)}
System call to CLear-ALL I/O devices to the default values. See the Programmers Reference Guide.
DL (--- addr1)
A user variable which holds the current READ/WRITE device number, defaults to 1 for cassette.

EDIT (n1 ---)
Select the screen n1 for editing, select the EDITOR vocabulary, and go into the split screen mode. Enables the captured keys for cursor control.

EM (--- addr1)
A system variable, holds the end of memory pointer.

EMIT (b ---)
Transmit byte, b, to the selected output device. OUT is incremented for each character output. The output device is determined by the channel number contained in OUCH, and what file is opened on that channel.

Ff (--- addr1)
A user variable which holds the current file number for all READ/WRITE operations. Defaults to 1 for cassette operation.

FN (--- addr1)
A user variable which holds the name of the current READ/WRITE file. This buffer is 64 characters long.

H. (n1 ---)
Print the value n1 from the stack to the current output device, as an unsigned hexadecimal number.

I/O (--- addr1)
A user variable which returns the beginning address of the I/O vector table area. See 5.2 for the positions of each of the vectored words in the table.

NAME  ( --- )
Accept the text following NAME until a delimiting up-arrow character or a <return> is entered. Place the text into user array FN, with the count byte in the first char of FN.

NOISE  ( --- addr1 )
A system constant which returns the address of the NOISE voice of the VIC chip; values between 128 and 255 turn the voice on.

OPEN  ( --- )
A system command which opens the filename, file number, and device just specified in the last SETFLS and SETNAM commands.

PRINT  ( --- )
Print any output from the line of commands following the print command to the serial bus printer, device E4.

PRON  ( --- )
Send all terminal output to the serial bus printer, device number 4. Can be restored by CLALL.

READ  ( nl --- )
Read the first screen from the current device as specified by DL and FL, into screen nl. Normally will read from cassette, but can be made to read from disk, by changing DL, FL, and specifying a name for the file. Will read named files from cassette,
by specifying a name for the cassette file.

READS ( n1/n2 --- )
Read from cassette to screen n1 through n1+n2. The value n2 is the quantity of screens to read. This word can not be made to read screens from disk, since each disk screen must have a different name.

SAVE ( addr1/n1 --- )
Save the data or program from address addr1 for a count of n1 bytes to the currently open mass storage device.

SETFLS ( n1/n2/n3 --- )
Set the logical file with filenumber n1, device number n2, and secondary command n3 into the operating system.

SETNAM ( addr1/n1 --- )
Set the string at address addr1 for count n1 as the name of the current mass storage file name.

SYS ( <f1>/n1/n2/n3/addr1 --- <f1>/n4/n5/n6 )
Perform a system call to an assembly language routine, at address addr1, with the cpu registers A,X,Y as values n1,n2,n3. Pass optional flag <f1> as the carry state. Return n4,n5,n6 as the cpu registers A,X,Y and return <f1> unmodified.

SLOAD ( addr1 --- )
Load the program from the current device, into address addr1. The length of the load is determined by the file being loaded.

SOPRANO ( --- addr1 )
A system constant, which returns the address of the SOPRANO voice in the VIC chip. Values between 128
and 255 turn this voice on.

TENOR ( --- addr1 )
A system constant which returns the address of the TENOR voice in the VIC chip. Values between 128 and 255 turn this voice on.

THRU ( n1/n2 --- )
Load screens n1 through screen n2, from the screen buffers already in memory. DOES-NOT read any screens from cassette.

UK ( n1/n2 --- f1 )
Perform an unsigned less than comparison on n1 and n2. Return boolean flag f1 true if n1 is less than n2.

U. ( ul --- )
Print the number ul to the currently selected output device, as an unsigned number in the current base.

UPORT ( --- addr1 )
A system constant, returns the address of the USER port.

VECTOR ( n1 --- )
A defining word used in the form:
   n1 VECTOR nnnn
To create a word 'nnnn' which when executed will itself execute the contents of the n1 vectored routine in the I/O table. User created vectored words must start at value 30 decimal and must not be higher than 50.

VOLUME ( n1 --- )
Values between 0 and 15 decimal control the VOLUME of all the voices in the VIC chip.

(C) 1982 Human Engineered Software
VRESET  ( --- )
Reset all I/O vectors to their default values as held in the default table VWORDS. The values of FL and DL are also reset to 1.

VWORDS  ( --- addr1 )
This word returns the address addr1 of the beginning of the initial value vector table in ROM. See section 5.2 for the positions of the vectored words in the table.

WRITE  ( nl --- )
Write screen nl to the current device, as specified by DL and FL. The written screen will be sent to cassette unless DL and FL are set for disk.

WRITES  ( nl/n2 --- )
Screens nl through nl+n2 will be written to cassette. Can not be made to write to disk.
fig-FORTH GLOSSARY

This glossary contains all of the word definitions in Release I of fig-FORTH. The definitions are presented in the order of their ASCII sort.

The first line of each entry shows a symbolic description of the action of the procedure on the parameter stack. The symbols indicate the order in which input parameters have been placed on the stack. Three dashes "---" indicate the execution point; any parameters left on the stack are listed. In this notation, the top of the stack is to the right.

The symbols include:

addr memory address
b 8 bit byte (i.e. hi 8 bits zero)
c 7 bit ascii character (hi 9 bits zero)
d 32 bit signed double integer, most significant portion with sign on top of stack.
f boolean flag. 0=false, non-zero=true
ff boolean false flag=0
n 16 bit signed integer number
u 16 bit unsigned integer

tf boolean true flag=non-zero

The capital letters on the right show definition characteristics:

C May only be used within a colon definition. A digit indicates number of memory addresses used, if other than one.

E Intended for execution only.

LO Level Zero definition of FORTH-78

L1 Level One definition of FORTH-78

P Has precedence bit set. Will execute even when compiling.

U A user variable.

Unless otherwise noted, all references to numbers are for 16 bit signed integers. On 8 bit data bus computers, the high byte of a number is on top of the stack, with the sign in the leftmost bit. For 32 bit signed double numbers, the most significant part (with the sign) is on top.

All arithmetic is implicitly 16 bit signed integer math, with error and underflow indication unspecified.

1 n addr --- LO
Store 16 bits of n at address. Pronounced "store".

ICSP
Save the stack position in CSP. Used as part of the compiler security.

f d1 --- d2 LO
Generate from a double number d1, the next ascii character which is placed in an output string. Result d2 is the quotient after division by BASE, and is maintained for further processing. Used between #f and $f. See $f.

f> d --- addr count LO
Terminates numeric output conversion by dropping d, leaving the text address and character count suitable for TYPE.
Generates ascii text in the text output buffer, by the use of $\#$, until a zero double number $n2$ results. Used between $<$ and $>$.

$\#d1 \ldots d2\text{ LO}\$

--- addr

Used in the form:

\[ nnnn \]

Leaves the parameter field address of dictionary word $nnnn$. As a compiler directive, executes in a colon-definition to compile the address as a literal. If the word is not found after a search of CONTEXT and CURRENT, an appropriate error message is given. Pronounced "tick".

$\#P,LO$

Used in the form:

\[ cccc \]

Ignore a comment that will be delimited by a right parenthesis on the same line. May occur during execution or in a colon-definition. A blank after the leading parenthesis is required.

\[ (.,) \]

The run-time procedure, compiled by \[ C+ \]

which transmits the following in-line text to the selected output device. See ."

\[ (;CODE) \]

The run-time procedure, compiled by \[ C \]

;CODE, that rewrites the code field of the most recently defined word to point to the following machine code sequence. See ;CODE.

\[ (+LOOP) \]

n ---

The run-time procedure compiled by +LOOP, which increments the loop index by $n$ and tests for loop completion. See +LOOP.

\[ (ABORT) \]

Executes after an error when WARNING is -1. This word normally executes ABORT, but may be altered (with care) to a user's alternative procedure.

\[ (DO) \]

The run-time procedure compiled by DO which moves the loop control parameters to the return stack. See DO.

\[ (FIND) \]

addr1 addr2 --- psa b tf (ok)
addr1 addr2 --- ff (bad)

Searches the dictionary starting at the name field address addr2, matching to the text at addr1. Returns parameter field address, length byte of name field and boolean true for a good match. If no match is found, only a boolean false is left.

\[ (LINE) \]

n1 n2 --- addr count

Convert the line number $n1$ and the screen $n2$ to the disc buffer address containing the data. A count of 64 indicates the full line text length.

\[ (LOOP) \]

The run-time procedure compiled by LOOP which increments the loop index and tests for loop completion. See LOOP.

\[ (NUMBER) \]

d1 addr1 --- d2 addr2

Convert the ascii text beginning at addr1+1 with regard to BASE. The new value is accumulated into double number $d1$, being left as $d2$. Addr2

---

FORTH INTEREST GROUP ..... P.O. Box 1105 ..... San Carlos, Ca. 94070
is the address of the first unconvertible digit. Used by NUMBER.

*  n1 n2 -- prod   L0
Leave the signed product of two
signed numbers.

*/  n1 n2 n3 -- n4   L0
Leave the ratio n4 = n1*n2/n3
where all are signed numbers. Reten-
tion of an intermediate 31 bit
product permits greater accuracy than
would be available with the sequence:
   n1 n2 * n3 /

*/MOD n1 n2 n3 -- n4 n5   L0
Leave the quotient n5 and remainder
n4 of the operation n1*n2/n3
A 31 bit intermediate product is
used as for */.

+  n1 n2 -- sum   L0   +ORIGIN
Leave the sum of n1+n2.

+!  n addr --   L0
Add n to the value at the address.
Pronounced "plus-store".

++  n1 n2 -- n3   L0
Apply the sign of n2 to n1, which
is left as n3.

+BUF  addr1 -- addr2 f
Advance the disc buffer address addr1
to the address of the next buffer
addr2. Boolean f is false when addr2
is the buffer presently pointed to
by variable PREV.

+LOOP  n1 -- (run)
addr n2 -- (compile) P,C2,L0
Used in a colon-definition in the
form:
   DO ... n1 +LOOP
At run-time, +LOOP selectively
controls branching back to the cor-
responding DO based on n1, the loop
index and the loop limit. The signed
increment n1 is added to the index
and the total compared to the limit.
The branch back to DO occurs until
the new index is equal to or greater
than the limit (n1>0), or until the
new index is equal to or less than
the limit (n1<0). Upon exiting the
loop, the parameters are discarded
and execution continues ahead.

At compile time, +LOOP compiles
the run-time word (+LOOP) and the
branch offset computed from HERE to
the address left on the stack by
DO. n2 is used for compile time
error checking.

n -- addr
Leave the memory address relative
by n to the origin parameter area.
In the minimum address unit, either
byte or word. This definition is used
to access or modify the boot-up
parameters at the origin area.

n --   L0
Store n into the next available dic-
tionary memory cell, advancing the
dictionary pointer. (comma)

n1 n2 -- diff   L0
Leave the difference of n1-n2.

P,L0
Continue interpretation with the
next disc screen. (pronounced
next-screen).
-DUP n1 -- n1 (if zero)
n1 -- n1 n1 (non-zero) L0

Reproduce n1 only if it is non-zero.
This is usually used to copy a value
just before IF, to eliminate the need
for an ELSE part to drop it.

-FIND --- pfa b tf (found)
--- ff (not found)
Accepts the next text word (delimited
by blanks) in the input stream to
HERE, and searches the CONTEXT and
then CURRENT vocabularies for a
matching entry. If found, the
dictionary entry's parameter field
address, its length byte, and a
boolean true is left. Otherwise,
only a boolean false is left.

-TRAILING addr n1 --- addr n2
Adjusts the character count n1 of a
text string beginning address to
suppress the output of trailing
blanks. i.e. the characters at
addr+n1 to addr+n2 are blanks.

n --- L0
Print a number from a signed 16 bit
two's complement value, converted
according to the numeric BASE.
A trailing blanks follows.
Printed "dot".

",

Used in the form:
" cccc"
Compiles an in-line string cccc
(delimited by the trailing ") with an
execution procedure to transmit the
text to the selected output device.
If executed outside a definition, "
will immediately print the text until
the final ". The maximum number of
characters may be an installation
dependent value. See (" ").

-LINE
Print on the terminal device, a line
of text from the disc by its line and
screen number. Trailing blanks are
suppressed.

-1**
Print the number n1 right aligned in
a field whose width is n2. No
following blank is printed.

/ --- n1 n2 --- quot L0
Leave the signed quotient of n1/n2.

-1/3**
Leave the remainder and signed
quotient of n1/n2. The remainder
has the sign of the dividend.

123
These small numbers are used so often
that it is attractive to define them
by name in the dictionary as const-
ants.

0< --- n --- f L0
Leave a true flag if the number is
less than zero (negative), otherwise
leave a false flag.

0= --- n --- f L0
Leave a true flag if the number is
equal to zero, otherwise leave a
false flag.

f --- C2
The run-time procedure to condition-
ally branch. If f is false (zero),
the following in-line parameter is
added to the interpretive pointer to
branch ahead or back. Compiled by
IF, UNTIL, and WHILE.
Increment n1 by 1.

Leave n1 incremented by 2.

Used in the form called a colon-definition:

create a dictionary entry defining cccc as equivalent to the following sequence of Forth word definitions '.....' until the next ';' or ';'CODE.'.

The compiling process is done by the text interpreter as long as STATE is non-zero. Other details are that the CONTEXT vocabulary is set to the CURRENT vocabulary and that words with the precedence bit set (P) are executed rather than being compiled.

Terminate a colon-definition and stop further compilation. Compiles the run-time ;S.

Used in the form:

Stop compilation and terminate a new defining word cccc by compiling (;CODE). Set the CONTEXT vocabulary to ASSEMBLER, assembling to machine code the following mnemonics.

When cccc later executes in the form:

the word nnnn will be created with its execution procedure given by
by the machine code following cccc.
That is, when nnnn is executed, it does so by jumping to the code after
nnnn. An existing defining word must exist in cccc prior to ;CODE.

Stop interpretation of a screen.

;S is also the run-time word compiled at the end of a colon-definition which returns execution to the calling procedure.

Leave a true flag if n1 is less than n2; otherwise leave a false flag.

Setup for pictorial numeric output formatting using the words: ;S / # SIGN /#

The conversion is done on a double number producing text at PAD.

Used within a colon-definition:

Each time cccc is executed, ;BUILDS defines a new word with a high-level execution procedure. Executing cccc in the form:

uses ;BUILDS to create a dictionary entry for nnnn with a call to the DOES> part for nnnn. When nnnn is later executed, it has the address of its parameter area on the stack and executes the words after DOES> in cccc. ;BUILDS and DOES> allow run-time procedures to be written in high-level rather than in assembler code (as required by ;CODE).
**FORTH INTEREST GROUP •••• P.O. Box 1105 •••• San Carlos, Ca. 94070**
AND n1 n2 ===> n2
Leave the bitwise logical and of n1
and n2 as n3.

B/BDF --- n
This constant leaves the number of
bytes per disc buffer, the byte count
read from disc by BLOCK.

B/SCR --- n
This constant leaves the number of
blocks per editing screen. By con-
vention, an editing screen is 1024
bytes organized as 16 lines of 64
characters each.

BACK --- addr
Calculate the backward branch offset
from HERE to addr and compile into
the next available dictionary memory
address.

BASE --- addr
A user variable containing the current
number base used for input and out-
put conversion.

BEGIN --- addr n (compiling) P,L0
Occurs in a colon-definition in form:
BEGIN ... UNTIL
BEGIN ... AGAIN
BEGIN ... WHILE ... REPEAT
At run-time, BEGIN marks the start
of a sequence that may be repetitive-
ly executed. It serves as a return
point from the corresponding UNTIL,
AGAIN or REPEAT. When executing
UNTIL, a return to BEGIN will occur
if the top of the stack is false;
for AGAIN and REPEAT a return to
BEGIN always occurs.
At compile time BEGIN leaves its re-
turn address and n for compiler error
checking.

BL --- c
A constant that leaves the ascii
value for "blank".

BLANKS addr count ---
Fill an area of memory beginning at
addr with blanks.

BLK --- addr
An user variable containing the block
number being interpreted. If zero,
input is being taken from the term-
inal input buffer.

BLOCK n --- addr L0
Leave the memory address of the block
buffer containing block n. If the
block is not already in memory, it is
transferred from disc to which ever
buffer was least recently written.
If the block occupying that buffer
has been marked as updated, it is re-
written to disc before block n is
read into the buffer. See also
BUFFER, R/W UPDATE FLUSH

BLOCK-READ

BLOCK-WRITE These are the preferred names
for the installation dependent code
to read and write one block to the
disc.

BEGIN ... UNTIL
BEGIN ... AGAIN
BEGIN ... WHILE ... REPEAT

BRANCH C2,L0
The run-time procedure to uncondi-
tionally branch. An in-line offset
is added to the interpretive pointer
IP to branch ahead or back. BRANCH
is compiled by ELSE, AGAIN, REPEAT.

BUFFER --- addr
Obtain the next memory buffer, ass-
ing it to block n. If the con-
tents of the buffer is marked as up-
dated, it is written to the disc.
The block is not read from the disc.
The address left is the first cell within the buffer for data storage.

C1
b addr --
Store 8 bits at address. On word addressing computers, further specification is necessary regarding byte addressing.

C2

b ---
Store 8 bits of b into the next available dictionary byte, advancing the dictionary pointer. This is only available on byte addressing computers, and should be used with caution on byte addressing mini-computers.

C6
addr -- b
Leave the 8 bit contents of memory address. On word addressing computers, further specification is needed regarding byte addressing.

CFA
pfa --- cfa
Convert the parameter field address of a definition to its code field address.

C-MOVE
from to count ---
Move the specified quantity of bytes beginning at address from to address to. The contents of address from is moved first proceeding toward high memory. Further specification is necessary on word addressing computers.

COLD
The cold start procedure to adjust the dictionary pointer to the minimum standard and restart via ABORT. May be called from the terminal to remove application programs and restart.

COMPIL C2
When the word containing COMPIL executes, the execution address of the word following COMPIL is copied (compiled) into the dictionary. This allows specific compilation situations to be handled in addition to simply compiling an execution address (which the interpreter already does).

CONSTANT
n --
A defining word used in the form: n CONSTANT cccc to create word cccc, with its parameter field containing n. When cccc is later executed, it will push the value of n to the stack.

CONTEXT
--- addr
U,10 A user variable containing a pointer to the vocabulary within which dictionary searches will first begin.

COUNT
addr1 --- addr2 n
Leave the byte address addr2 and byte count n of a message text beginning at address addr1. It is presumed that the first byte at addr1 contains the text byte count and the actual text starts with the second byte. Typically COUNT is followed by TYPE.

CR
Transmit a carriage return and line feed to the selected output device.

CREATE
A defining word used in the form: CREATE cccc

FORTH INTEREST GROUP P.O. Box 1105 San Carlos, Ca. 94070
by such words as CODE and CONSTANT to create a dictionary header for a Forth definition. The code field contains the address of the words parameter field. The new word is created in the CURRENT vocabulary.

CSP

--- addr U
A user variable temporarily storing the stack pointer position, for compilation error checking.

D+
d1 d2 --- dsum Leave the double number sum of two double numbers.

D+-
d1 n --- d2 Apply the sign of n to the double number d1, leaving it as d2.

D. d --- L1
Print a signed double number from a 32 bit two’s complement value. The high-order 16 bits are most accessible on the stack. Conversion is performed according to the current BASE. A blank follows. Pronounced D-dot.

D.R d n ---
Print a signed double number d right aligned in a field n characters wide.

DABS d --- uL Leave the absolute value ud of a double number.

DECIMAL

Set the numeric conversion BASE for decimal input-output.

DEFINITIONS

Used in the form:

cccc DEFINITIONS
Set the CURRENT vocabulary to the CONTEXT vocabulary. In the example, executing vocabulary name cccc made it the CONTEXT vocabulary and executing DEFINITIONS made both specify vocabulary cccc.

DIGIT
c n1 --- n2 tf (ok) c n1 --- ff (bad)
Converts the ascii character c (using base nl) to its binary equivalent n2, accompanied by a true flag. If the conversion is invalid, leaves only a false flag.

DLIST

List the names of the dictionary entries in the CONTEXT vocabulary.

DLITERAL
d --- d (executing) d --- (compiling) P
If compiling, compile a stack double number into a literal. Later execution of the definition containing the literal will push it to the stack. If executing, the number will remain on the stack.

DMINUS
d1 --- d2
Convert d1 to its double number two’s complement.

DO
n1 n2 --- (execute) addr n --- (compile) P,C2;LO
Occur in a colon-definition in form:

DO ... LOOP
DO ... +LOOP
At run time, DO begins a sequence with repetitive execution controlled by a loop limit n1 and an index with initial value n2. DO removes these from the stack. Upon reaching LOOP the index is incremented by one. Until the new index equals or exceeds
the limit, execution loops back to
just after DO; otherwise the loop
parameters are discarded and execu-
tion continues ahead. Both n1 and n2
are determined at run-time and may be
the result of other operations.
Within a loop '1' will copy the
next value of the index to the
stack. See I, LOOP, +LOOP, LEAVE.

When compiling within the colon-
definition, DO compiles (DO), leaves
the following address addr and n for
later error checking.

**DOES**

A word which defines the run-time
action within a high-level defining
word. DOES> alters the code field
and first parameter of the new word
to execute the sequence of compiled
word addresses following DOES>. Used
in combination with <BUILDS>. When the
DOES> part executes it begins with
the address of the first parameter
of the new word on the stack. This
allows interpretation using this
area or its contents. Typical uses
include the FORTH assembler, multi-
dimensional arrays, and compiler
generation.

**DP**

A user variable, the dictionary
pointer, which contains the address
of the next free memory above the
dictionary. The value may be read by
HERE and altered by ALLOT.

**DPL**

A user variable containing the number
of digits to the right of the decimal
on double integer input. It may also

--- addr U,L

--- addr U,LO

--- addr

be used hold output column location
of a decimal point, in user generated
formatting. The default value on
single number input is -1.

Installation dependent commands to
select disc drives, by presetting
OFFSET. The contents of OFFSET is
added to the block number in BLOCK
to allow for this selection. Offset
is suppressed for error text so that
it may always originate from drive 0.

--- n ---

Drop the number from the stack.

--- addr n ---

Print the contents of n memory
locations beginning at addr. Both
addresses and contents are shown in
the current numeric base.

n --- n ---

Duplicate the value on the stack.

--- addr1 n1 --- addr2 n2

(compiling) P,C2,LO

Occurs within a colon-definition
in the form:

IF ... ELSE ... ENDIF

At run-time, ELSE executes after the
two part following IF. ELSE forces
execution to skip over the following
false part and resumes execution
after the ENDIP. It has no stack
effect.

At compile-time ELSE replaces BRANCH
reserving a branch offset, leaves
the address addr2 and n2 for error
testing. ELSE also resolves the
remaining forward branch from IF by
calculating the offset from addr1 to
HERE and storing at addr1.
EMIT

```
EMIT c --
Transmit ascii character c to the
selected output device. OUT is
incremented for each character
output.
```

EMPTY-BUFFERS

```
EMPTY-BUFFERS
Mark all block-buffers as empty, not
necessarily affecting the contents.
Updated blocks are not written to the
disc. This is also an initialization
procedure before first use of the
disc.
```

ENCLOSE

```
ENCLOSE addr1 c --
ddr1 n1 n2 n3
The text scanning primitive used by
WORD. From the text address addr1
and an ascii delimiting character c,
is determined the byte offset to the
first non-delimiter character n1,
the offset to the first delimiter
after the text n2, and the offset
to the first character not included.
This procedure will not process past
an ascii 'null', treating it as an
unconditional delimiter.
```

END

```
END
This is an 'alias' or duplicate
definition for DML.
```

ENDIF

```
EndIF
addr n -- (compile) P,C0,LO
Occurs in a colon-definition in form:
IF ... ENDF
IF ... ELSE ... ENDF
At run-time, ENDF serves only as the
destination of a forward branch from
IF or ELSE. It marks the conclusion
of the conditional structure. THEN
is another name for ENDIF. Both
names are supported in fig-FORTH. See
also IF and ELSE.
```

At compile-time, ENDF computes the
forward branch offset from addr to
HERE and stores it at addr. n is
used for error tests.

ERASE

```
ERASE
addr n --
Clear a region of memory to zero from
addr over n addresses.
```

ERROR

```
ERROR
line -- in blk
Execute error notification and re-
start of system. WARNING is first
examined. If 1, the text of line n,
relative to screen 4 of drive 0 is
printed. This line number may be
positive or negative, and beyond just
screen 4. If WARNING = 0, n is just
printed as a message number (non-disc
installation). If WARNING = -1,
the definition (ABORT) is executed,
which executes the system ABORT. The
user may cautiously modify this
execution by altering (ABORT).
fig-FORTE saves the contents of IN
and BLK to assist in determining the
location of the error. Final action
is execution of QUIT.
```

EXECUTE

```
EXECUTE
addr --
Execute the definition whose code
field address is on the stack. The
code field address is also called
the compilation address.
```

EXPECT

```
EXPECT
addr count --
Transfer characters from the terminal
to address, until a "return" or the
count of characters have been re-
evived. One or more nulls are added
at the end of the text.
```

FORTH INTEREST GROUP ···· P.O. Box 1105 ···· San Carlos, Ca. 94070
FENCE --- addr U HEX
A user variable containing an
address below which FORGOTTening is
trapped. To forget below this point
the user must alter the contents of
FENCE.

FILL addr quan b ---
Fill memory at the address with the
specified quantity of bytes b.

FIRST --- n I
A constant that leaves the address
of the first (lowest) block buffer.

FLD --- addr U
A user variable for control of number
output field width. Presently un-
used in fig-FORTH.

FORGET
Executed in the form:
FORGET cccc
Deletes definition named cccc from
the dictionary with all entries
physically following it. In fig-
FORTH, an error message will occur if
the CURRENT and CONTEXT vocabularies
are not currently the same.

FORTH P.C1
The name of the primary vocabulary.
Execution makes FORTH the CONTEXT
vocabulary. Until additional user
vocabularies are defined, new user
definitions become a part of FORTH.
FORTH is immediate, so it will exec-
ute during the creation of a colon-
definition, to select this vocabulary
at compile time.

HERE --- addr LO
Leave the address of the next avail-
able dictionary location.

FORTH INTEREST GROUP ...... P.O. Box 1105 ...... San Carlos, Ca. 94070

Set the numeric conversion base to
sixteen (hexadecimal).

HLD --- addr LO
A user variable that holds the addr-
ness of the latest character of text
during numeric output conversion.

c --- LO
Used between # and # to insert
an ascii character into a pictured
numeric output string.
e.g. 2E HELD will place a
decimal point.

CLO --- n C.LO
Used within a DO-LOOP to copy the
loop index to the stack. Other
use is implementation dependent.
See R.

addr ---
Print a definition's name from its
name field address.

f --- (run-time)
 -- addr n (compile) P.C2,LO
Occurs in a colon-definition in form:
IF (tp) ... ENDF
IF (tp) ... ELSE (fp) ... ENDF
At run-time, IF selects execution
based on a boolean flag. If f is
true (non-zero), execution continues
ahead thru the true part. If f is
false (zero), execution skips till
just after ELSE to execute the false
part. After either part, execution
resumes after ENDF. ELSE and its
false part are optional; if missing,
false execution skips to just after
ENDIF.
At compile-time IF compiles OBRANCH and reserves space for an offset at addr. addr and n are used later for resolution of the offset and error testing.

**IMMEDIATE**

Mark the most recently made definition so that when encountered at compile time, it will be executed rather than being compiled. i.e. the precedence bit in its header is set. This method allows definitions to handle unusual compiling situations, rather than build them into the fundamental compiler. The user may force compilation of an immediate definition by preceding it with \[\text{COMPILe}\].

**IN**

--- addr LO
A user variable containing the byte offset within the current input text buffer (terminal or disc) from which the next text will be accepted. WORD uses and moves the value of IN.

**INDEX**

from to ---
Print the first line of each screen over the range from, to. This is used to view the comment lines of an area of text on disc screens.

**INTERPRET**

The outer text interpreter which sequentially executes or compiles text from the input stream (terminal or disc) depending on STATE. If the word name cannot be found after a search of CONTEXT and then CURRENT it is converted to a number according to the current base. That also failing, an error message echoing the name with a "?" will be given.

Text input will be taken according to the convention for WORD. If a decimal point is found as part of a number, a double number value will be left. The decimal point has no other purpose than to force this action. See NUMBER.

**KEY**

--- c LO
Leave the ascii value of the next terminal key struck.

**LATEST**

--- addr
Leave the name field address of the topmost word in the CURRENT vocabulary.

**LEAVE**

Force termination of a DO-LOOP at the next opportunity by setting the loop limit equal to the current value of the index. The index itself remains unchanged, and execution proceeds normally until LOOP or +LOOP is encountered.
LFA
   pfa --- lfa
   Convert the parameter field address
   of a dictionary definition to its
   link field address.

LIMIT
   --- n
   A constant leaving the address just
   above the highest memory available
   for a disc buffer. Usually this is
   the highest system memory.

LIST
   n --- L0
   Display the ascii text of screen n
   on the selected output device. SCR
   contains the screen number during and
   after this process.

LIT
   --- n C2,L0
   Within a colon-definition, LIT is
   automatically compiled before each
   16 bit literal number encountered in
   input text. Later execution of LIT
   causes the contents of the text
   dictionary address to be pushed to
   the stack.

LITERAL
   n --- (compiling) P,C2,L0
   If compiling, then compile the stack
   value n as a 16 bit literal. This
   definition is immediate so that it
   will execute during a colon-defini-
   tion. The intended use is:
   : xxx [ calculate ] LITERAL ;
   Compilation is suspended for the
   compile time calculation of a value.
   Compilation is resumed and LITERAL
   compiles this value.

LOAD
   n --- LO
   Begin interpretation of screen n.
   Loading will terminate at the end
   of the screen or at ;S. See ;S and -->

LOOP
   addr n --- (compiling) P,C2,L0
   Occurs in a colon-definition in form:
   DO ... LOOP
   At run-time, LOOP selectively con-
   trols branching back to the correspon-
   ding DO based on the loop index and
   limit. The loop index is incremented
   by one and compared to the limit. The
   branch back to DO occurs until the
   index equals or exceeds the limit;
   at that time, the parameters are
   discarded and execution continues
   ahead.
   At compile-time, LOOP compiles (LOOP)
   and uses addr to calculate an offset
   to DO. n is used for error testing.

M* n1 n2 --- d
   A mixed magnitude math operation
   which leaves the double number signed
   product of two signed number.

M/ d n1 --- n2 n3
   A mixed magnitude math operator which
   leaves the signed remainder n2 and
   signed quotient n3, from a double
   number dividend and divisor n1. The
   remainder takes its sign from the
   dividend.

FORTH INTEREST GROUP ···· P.O. Box 1105 ···· San Carlos, Ca. 94070
M/MOD

ud1 u2 --- u3 ud4
An unsigned mixed magnitude math operation which leaves a double quotient ud4 and remainder u3, from a double dividend ud1 and single divisor u2.

MAX

n1 n2 --- max
Leave the greater of two numbers.

MESSAGE

n ---
Print on the selected output device the text of line n relative to screen 4 of drive 0. n may be positive or negative. MESSAGE may be used to print incidental text such as report headers. If WARNING is zero, the message will simply be printed as a number (disc un-available).

MIN

n1 n2 --- min
Leave the smaller of two numbers.

MINUS

n1 --- n2
Leave the two's complement of a number.

MOD

n1 n2 --- mod
Leave the remainder of n1/n2, with the same sign as n1.

MON

Exit to the system monitor, leaving a re-entry to Forth, if possible.

MOVE

addr1 addr2 n ---
Move the contents of n memory cells (16 bit contents) beginning at addr1 into n cells beginning at addr2. The contents of addr1 is moved first. This definition is appropriate on word addressing computers.

This is the inner interpreter that uses the interpretive pointer IP to execute compiled Forth definitions. It is not directly executed but is the return point for all code procedures. It acts by fetching the address pointed by IP, storing this value in register W. It then jumps to the address pointed to by the address pointed to by W. W points to the code field of a definition which contains the address of the code which executes for that definition. This usage of indirect threaded code is a major contributor to the power, portability, and extensibility of Forth. Locations of IP and W are computer specific.

pfa --- nfa
Convert the parameter field address of a definition to its name field.

addr --- d
Convert a character string left at addr with a preceding count, to a signed double number, using the current numeric base. If a decimal point is encountered in the text, its
position will be given in DPL, but no other effect occurs. If numeric conversion is not possible, an error message will be given.

OFFSET  -- addr  U
A user variable which may contain a block offset to disk drives. The contents of OFFSET is added to the stack number by BLOCK. Messages by MESSAGE are independent of OFFSET. See BLOCK, DRI, DRI, MESSAGE.

OR      n1 n2 -- or  LO
Leave the bit-wise logical or of two 16 bit values.

OUT     -- addr  U
A user variable that contains a value incremented by EMIT. The user may alter and examine OUT to control display formatting.

OVER    n1 n2 --- n1 n2 n1  LO
Copy the second stack value, placing it as the new top.

PAD     -- addr  LO
Leave the address of the text output buffer, which is a fixed offset above HERE.

PFA     nfa --- pfa
Convert the same field address of a compiled definition to its parameter field address.

POP
The code sequence to remove a stack value and return to NEXT. POP is not directly executable, but is a Forth re-entry point after machine code.

PREV    -- addr
A variable containing the address of the disc buffer most recently referenced. The UPDATE command marks this buffer to be later written to disc.

PUSH
This code sequence pushes machine registers to the computation stack and returns to NEXT. It is not directly executable, but is a Forth re-entry point after machine code.

PUT
This code sequence stores machine register contents over the topmost computation stack value and returns to NEXT. It is not directly executable, but is a Forth re-entry point after machine code.

QUERY
Input 80 characters of text (or until a "return") from the operator terminal. Text is positioned at the address contained in TIB with IN set to zero.

FORTH INTEREST GROUP •••• P.O. Box 1105 •••• San Carlos, Ca. 94070
QUIT

Clear the return stack, stop compilation, and return control to the operators terminal. No message is given.

--- n

Copy the top of the return stack to the computation stack.

--- addr

A user variable which may contain the location of an editing cursor, or other file related function.

addr blk f ---
The fig-FORTH standard disc read-write linkage. addr specifies the source or destination block buffer, blk is the sequential number of the referenced block, and f is a flag for f=0 write and f=1 read.

R/W determines the location on mass storage, performs the read-write and performs any error checking.

--- n

Remove the top value from the return stack and leave it on the computation stack. See >R and R.

RO

A user variable containing the initial location of the return stack. Pronounced R-zero. See RPI.

addr n --- (compiling) P,C2

Used within a colon-definition in the form:

BEGIN ... WHILE ... REPEAT

At run-time, REPEAT forces an unconditional branch back to just after the corresponding BEGIN.

At compile-time, REPEAT compiles BRANCH and the offset from HERE to addr. n is used for error testing.

nl n2 n3 --- n2 n3 nl L0

Rotate the top three values on the stack, bringing the third to the top.

A computer dependent procedure to initialize the return stack pointer from user variable RO.

n --- d

Sign extend a single number to form a double number.

--- addr

A user variable that contains the initial value for the stack pointer. Pronounced S-zero. See SP!

SCR

A user variable containing the screen number most recently reference by LIST.
SIGN

n d --- d
Stores an ascii "-" sign just before a converted numeric output string in the text output buffer when n is negative. n is discarded, but double number d is maintained. Must be used between <# and >#.

SMUDGE

Used during word definition to toggle the "smudge bit" in a definitions' name field. This prevents an uncompleted definition from being found during dictionary searches, until compiling is completed without error.

SP!

A computer dependent procedure to initialize the stack pointer from S0.

SP@

--- addr
A computer dependent procedure to return the address of the stack position to the top of the stack, as it was before SP@ was executed. (e.g. 1 2 SP@ # . . . would type 2 2 1)

SPACE

Transmit an ascii blank to the output device.

SPACES

n ---
Transmit n ascii blanks to the output device.

STATE

--- addr
A user variable containing the compilation state. A non-zero value indicates compilation. The value itself may be implementation dependent.

SWAP

n1 n2 --- n2 n1
Exchange the top two values on the stack.

TASK

A no-operation word which can mark the boundary between applications. By forgetting TASK and re-compiling, an application can be discarded in its entirety.

THEN

An alias for ENDF.

P,C0,LO

TIB

--- addr
A user variable containing the address of the terminal input buffer.

TOGGLE

addr b ---
Complement the contents of addr by the bit pattern b.

TRAVERSE

addrl n --- addr2
Move across the name field of a fig-FORTH variable length name field. addrl is the address of either the length byte or the last letter. If n=1, the motion is toward hi memory; if n=-1, the motion is toward low memory. The addr2 resulting is address of the other end of the name.
Display on the selected output device the three screens which include that numbered scr., beginning with a screen evenly divisible by three. Output is suitable for source text records, and includes a reference line at the bottom taken from line 15 of screen 4.

Transmit count characters from addr to the selected output device.

Leave the unsigned double number product of two unsigned numbers.

Leave the unsigned remainder u2 and unsigned quotient u3 from the unsigned double dividend ud and unsigned divisor ul.

Occurs within a colon-definition in the form:

At compile-time, UNTIL compiles (OBRANCH) and an offset from HEK to addr n is used for error tests.

Marks the most recently referenced block (pointed to by PREV) as altered. The block will subsequently be transferred automatically to disc should its buffer be required for storage of a different block.

A variable containing the address of the block buffer to use next, as the least recently written.

A defining word used in the form:

n USER cccc
which creates a user variable cccc. The parameter field of cccc contains n as a fixed offset relative to the user pointer register UP for this user variable. When cccc is later executed, it places the sum of its offset and the user area base address on the stack as the storage address of that particular variable.
VARlABLE

A defining word used in the form:

VARIABLE cccc

When VARIABLE is executed, it creates
the definition cccc with its para-
meter field initialized to n. When
cccC is later executed, the address
of its parameter field (containing n)
is left on the stack, so that a fetch
or store may access this location.

WARNING

--- addr

A user variable containing a value
controlling messages. If = 1
disc is present, and screen 4 of
drive 0 is the base location for
messages. If = 0, no disc is present
and messages will be presented by
number. If = -1, execute (ABORT) for
a user specified proceedure.
See MESSAGE, ERROR.

VOC-LINK

--- addr

A user variable containing the addr-
ess of a field in the definition of
the most recently created vocabulary.
All vocabulary names are linked by
these fields to allow control for
FORGETTIng thru multiple vocabularies. WHILE

VOCABULARY

A defining word used in the form:

VOCABULARY cccc
to create a vocabulary definition
cccC. Subsequent use of cccc will
make it the CONTEXT vocabulary which
is searched first by INTERPRET. The
sequence "cccC DEFINITIONS" will
also make cccc the CURRENT vocabulary
into which new definitions are
placed.

In fig-FORTH, cccc will be so chained
to include all definitions of the
vocabulary in which cccc is itself
defined. All vocabularys ultimately
chain to Forth. By convention,
vocabulary names are to be declared
IMMEDIATE. See VOC-LINK.

List the names of the definitions in
the context vocabulary. "Break" will
terminate the listing.

f --- (run-time)

--- ad1 nl --- ad1 nl ad2 n2 P,C2

Occurs in a colon-definition in the
form:

BEGIN ... WHILE (tp) ... REPEAT
At run-time, WHILE selects condition-
al execution based on boolean flag f.
If f is true (non-zero), WHILE con-
tinues execution of the true part
which then branches back to BEGIN. If f is false (zero),
evaluation skips to just after REPEAT,
exitng the structure.

At compile time, WHILE emplaces
(OBRANCH) and leaves ad2 of the res-
erved offset. The stack values will
be resolved by REPEAT.
In fig-FORTH, a user variable containing the maximum number of letters saved in the compilation of a definitions' name. It must be 1 thru 31, with a default value of 31. The name character count and its natural characters are saved, up to the value in WIDTH. The value may be changed at any time within the above limits.

WORD c ---
Read the next text characters from the input stream being interpreted, until a delimiter c is found, storing the packed character string beginning at the dictionary buffer HERE. WORD leaves the character count in the first byte, the characters, and ends with two or more blanks. Leading occurrences of c are ignored. If BLK is zero, text is taken from the terminal input buffer, otherwise from the disc block stored in BLK.
See BLK, IN.

X
This is pseudonym for the "null" or dictionary entry for a name of one character of ascii null. It is the execution procedure to terminate interpretation of a line of text from the terminal or within a disc buffer, as both buffers always have a null at the end.

XOR n1 n2 --- xor
Leave the bitwise logical exclusive-or of two values.

[ ]
Used in a colon-definition in form:
: xxx [ words ] ... more ;
Suspend compilation. The words after [ are executed, not compiled. This allows calculation or compilation exceptions before resuming compilation with ]. See LITERAL, ].

\text{(COMPILE)}

P,C
Used in a colon-definition in form:
: xxx \text{(COMPILE)} \text{FORTH} ;
\text{(COMPILE)} \text{ will force the compilation of an immediate definition, that would otherwise execute during compilation. The above example will select the \text{FORTH} vocabulary when xxx executes, rather than at compile time.}

] \text{L1}
Resume compilation, to the completion of a colon-definition. See [ .}
